

GREENHOUSE GASES

According to the United States Environmental Protection Agency, gases that trap heat in the atmosphere are known as greenhouse gases.

Carbon dioxide, methane and nitrous oxide are three greenhouse gases that enter the Earth's atmosphere in different ways.

Carbon dioxide enters the atmosphere through the burning of fossil fuels, such as coal, natural gas and oil, solid waste, trees, and wood products. Carbon dioxide also can enter the atmosphere through chemical reactions like the manufacture of cement.

Methane enters the atmosphere through the production and transportation of coal, natural gas and oil. Livestock, certain agricultural practices and the decay of organic waste in solid waste landfills also produce methane emissions.

The combustion of fossil fuels and solid waste can produce nitrous oxide emissions, which also may enter the atmosphere during certain agricultural and industrial activities, including soil management practices and the production of synthetic commercial fertilizers.
