1st Annual Car-Bike-Tractor Show!
Date: Aug. 26
Local Vendors, Food and Music!
Location: Roadhouse 139 in Long Lake
Admission Fee: \$10.00

Fishes of Wisconsin

Black crappie

Common name: Black crappie
Scientific name: Pomoxis nigromaculatus (Pomoxis means "sharp opercle (cheek)"; nigromaculatus means "black spotted")
Distribution: The black crappie occurs in all three drainage basins in Wisconsin (Lake Michigan, Mississippi River, and Lake Superior). This glacial species is well distributed throughout the state, except in the streams of the driftless area of southwestern Wisconsin.

Spawning: In Wisconsin, the black crappie usually spawns in May and June; however, during a colder season, spawning may be delayed until July. Favorable spawning temperatures range from 64 to 68° F. The male sweeps out a nest in the sand or fine gravel and guards the young until they start to feed.
Angling: The black crappie is considered an excellent game fish when taken on light tackle. Extreme care must be taken in landing these fish because their mouths are very tender. Anglers spe-

cializing in catching black crappie know that to be successful the bait must be kept constantly moving. The best baits are small minnows, small maribou-covered jigs, plastic minnows, or small streamer flies cast along the outer edges of weed beds. The crappie lies in weed beds in deep water during the day and bites best in the early morning or toward evening. In summer, with the abundance of small fish for feed, they are more difficult to catch. Small minnows are used as bait in winter.

Bluegill

Common name: Bluegill
Scientific name: Lepomis macrochirus (Lepomis means "scaled cheek"; macrochirus means "large hand", possibly in reference to the size of the pectoral fin).
Distribution: Bluegill occurs in all three drainage basins in Wisconsin (Lake Michigan, Mississippi River, and Lake Superior). Originally it was not present in the Lake Superior basin, but as a result of

widespread stocking, it is now present and reproducing in many lakes and rivers.
Spawning: Spawning takes place from late May to early August (peaking in June) at water temperatures between 67 - 80° F. Males select a sand or gravel bar that can be hollowed out to form a nest. Before and after spawning, the male bluegill defends the nest against all species, but most vigorously against other male sunfishes.
Angling: Plain garden worms are the fa-

vorite bait for bluegills, but they can be caught on a number of different types of lures. The fly fisher can have fun with poppers, especially in spring and early summer, when nests are concentrated in shallow water. Most large bluegills are taken in deep water during the summer months by drifting with the wind using worms. Wintertime jigging in the weed beds with grubs or mousies on ice jigs also produces excellent results.
